

CSE108**HW05****Part 1 100pts**

In this homework you will write a game called "minesweeper" that player is going to open cells until the game will be terminated by "**win**" and returns the number of moves is made until win when the player finds every "un-mined" cells or by "**loose**" when they hits a mine.

The player will choose a cell either to open or to flag it until the game is terminated. Every time the player made a move the program should print whole grid with current moves, ask the player their next move and get their choice.

If a **closed** cell is chosen; it can be either opened or flagged.

If a **closed_empty** cell is chosen to open; it will be open, its 8 neighbor will be checked for emptiness and **empty neighbors** are also opened.

If a **closed_mined** cell is chosen to open; the game will be terminated by a loose message.

If a **flagged** cell is chosen; it can only be un-flagged.

If **all empty** cells are found; the game will be terminated by a win message.

You will print the grid with 'e' for empty cells; 'f' for flagged cells; '.' for closed cells.

In your code you will use an enumerated data type called "**cell**" as following

```
typedef enum {mined,
             empty,
             flaggedMined,
             flaggedEmpty,
             closedEmpty,
             closedMined,
             }cell;
```

The grid will be a GRIDSIZE x GRIDSIZE multi-dim array of **cell**.

Example : Assume we have a grid as below (**Initial Grid**), each move and its effect on the grid is colored by a different color.

.	.	.	.
.	.	.	.
.	.	.	.
.	.	.	.

Assume player made a choice to open the location of **(0,0)** (**1st Move**)

e	.	.	.
e	e	.	.
.	.	.	.
.	.	.	.
.	.	.	.

Now assume player wants to flag the location of **(0,1)** (**2nd Move**)

e	f	.	.
e	e	.	.
.	.	.	.
.	.	.	.
.	.	.	.

Now the player wants to open the location of **(3,3)** (**3rd Move**)

e	f	.	.
e	e	.	.
.	.	e	e
.	.	e	e
.	.	.	.

Now the player wants to open the location of **(0,3)** (**4th Move**)

e	f	.	e
e	e	.	.
.	.	e	e
.	.	e	e
.	.	.	.

Now the player wants to open **(3,0)** (**5th Move**)

e	f	.	e
e	e	.	.
e	e	e	e
e	e	e	e
.	.	.	.

Every closed-empty cells are open (number of moves : 5)
 A message will be printed "Congratulations! You win the game with 5 moves"
 (Here three closed-mined and one flagged-mined cells was not opened.)

Signature

```
void printGrid (cell grid[][GRIDSIZE]);
```

```
int openCell(cell grid[][GRIDSIZE], int x, int y); // return value int result = -2 when the  
cell is not opened with the case of illegal location; or flagged cell.
```

```
void flagCell(cell grid[][GRIDSIZE], int x, int y); // if a cell is wanted to be flagged; check  
if it is empty or mined: if it is empty, flag as flagged-empty; if it is mined, flag as  
flagged-mined
```

```
int isEmptyCell(cell grid[][GRIDSIZE], int x, int y); //return value int result=0 if the cell  
is not an empty cell and result=1 the cell is an empty cell.
```

```
int isLocationLegal(int x, int y); //return value int result=0 if the location is illegal and  
result=1 if the location is legal(in the grid).
```

```
int asMain(); // copy your main function into this function. Use the function to to take  
player's choice, to count their moves, and to call functions according to the player's wish.
```

```
void initGrid(cell grid[][GRIDSIZE]);
```

HINT

```
initGrid (); is a function to initialize your matrix as an arbitrary initial game board with  
closed-empty and closed-mined cells.
```

Good luck!
